Abstract – 1-Methoxy-6-nitroindole-3-carbaldehyde is proved to be a versatile electrophile and reacts regioselectively at the 2-position with various types of nucleophiles providing 2,3,6-trisubstituted indole derivatives. The reaction is applicable for the preparation of a novel pyrimido[1,2-*a*]indole derivative.

Indole is one of the electron rich hetero-aromatics. In the indole chemistry, therefore, electrophilic substitution reaction has been well studied² (as shown in general formula in Figure 1, A) and been applied to explain the biosyntheses of various types of indole alkaloids.²

It is evident, however, that some of natural products are difficult to produce by the electrophilic substitution reaction. Some examples are moroidin (**1**, Figure 2),^{3a} phalloidin (**2**),^{3b} goniomitine (**3**),^{3c} and so on.^{3d} They have either a C—N, a C—S, or a C—C bond at the 2 position of indole nucleus. Their syntheses require N⁺, S⁺, and C⁺ synthons, respectively. Except for S⁺ and C⁺, the N⁺ synthon is rarely available chemical species. If by chance a nucleophilic substitution reaction could be applied, their syntheses would become easy because the readily available N⁻ synthon would be employed. In the cases of **2** and **3**, the required S⁻ and C⁻ synthons have ample synthetic equivalents as well. Based on these ideas, we have thus far developed the unprecedented^{2,4} nucleophilic substitution reaction⁵ (as shown in general formula in Figure 1, **B**) simply by introducing a hydroxy or its modified group onto the nitrogen, N(1),⁵ of indole substrates.

In this paper, we wish to report that 1-methoxy-6-nitroindole-3-carbaldehyde (**4**) is an excellent substrate for achieving nucleophilic substitution reactions with variety of nucleophiles. Consequently, various types of 2,3,6-trisubstituted indole derivatives become readily available, providing useful building blocks for the syntheses of **1**, **2**, and **3**. Preparation of a novel pyrimido[1,2-*a*]indole derivative is also reported.

According to our synthetic method,⁶ we prepared 1-methoxy-6-nitroindole (**6**) from indoline (**5**) in 70% overall yield in 3 steps as shown in Scheme 1. Subsequent Vilsmeier-Haack reaction of **6** with POCl₃ and *N,N*-dimethylformamide (DMF) provided 1-methoxy-6-nitroindole-3-carbaldehyde (**4**) in 94% yield. Thus, **4** is now readily available from **5** in 4 steps in 66% overall yield.

With **4** in hand, we examined its nucleophilic substitution reaction with nitrogen-centered nucleophiles.

Using NaH as a base in DMF, piperidine was allowed to react with **4** at room temperature culminating in the formation of **7a** in 92% yield (Table 1).

Table 1

NuH	Reaction Time (h)	Compound 7	Nu	Yield (%)
	2.5	a		92
	3.5	b		98
	2.0	c		96
	1.5	d		97
	3.5	e		87

Under similar reaction conditions, pyrrole and indole provided **7b** and **7c** in 98 and 96% yields, respectively. Imidazole and benzimidazole also reacted with **4** providing **7d** and **7e** in the respective yields of 97 and 87%. Based on these successful results, we attempted the synthesis of **8**, a core structure of **1**. As expected, the reaction of *N*_α-Boc-L-histidine with **4** in DMF by the action of NaH as a base resulted in the formation of the desired *N*_α-Boc(3-formyl-6-nitroindol-2-yl)-L-histidine (**8**) in 94% yield.

We next examined NaSMe as a representative of sulfur-centered nucleophile. It reacted smoothly with **4** in DMF to afford **9** in 98% yield. In the next model experiment directed toward the phalloidin synthesis, *N*-acetyl-L-cysteine reacted successfully with **4** producing the expected *N*-acetyl-S-(3-formyl-6-nitroindol-2-yl)-L-cysteine (**10**) in 73% yield by the action of NaH in DMF.

As for a carbon nucleophile, we chose dimethyl malonate at first. In the presence of KO^tBu in DMF at room temperature, it reacted with **4** to give **11** in 92% yield. Next, in order to prepare a suitable synthetic intermediate for **3**, 3-acetylpyridine was allowed to react with **4** by the action of KH in THF. The desired **12** was successfully isolated in 92% yield.

On the other hand, we examined the reaction of **6** with *p*-chlorophenoxyacetonitrile (**13**) in the presence of KO^tBu in DMF at 0 °C and isolated vicarious⁷ product **14** in 67% yield (Scheme 2). It should be noted that, under similar reaction conditions, attempts to convert **4** to **15** by the reaction with **13** resulted in the formation of a novel 4-amino-3-*p*-chlorophenoxy-2-*p*-chlorophenoxy-methyl-7-nitropyrimido[1,2-*a*]indole-10-carbaldehyde (**16**) in 71% yield.

The structure of pyrimido[1,2-*a*]indole skeleton was determined as follows. First, **16** was converted to

10-methyl compound **17** in 93% yield by the treatment with Et₃SiH in refluxing TFA. Subsequent reaction of **17** with Ac₂O-pyridine at room temperature afforded 89% yield of **18**. The structure of **18** was determined by X-ray single crystallographic analysis and the results are shown in ORTEP drawing in Figure 4.

To clear the reaction mechanism for the formation of **16**, **13** was treated with KOtBu in DMF at 0°C in the absence of **4** resulting in the formation of a 41% yield of 3-amino-2-butenitrile **19** together with the recovery of **13**. Therefore, we can propose the following possible mechanism as shown in Scheme 3. By the reaction of KOtBu and **13**, rapid formation of **19** occurs and it is converted to the corresponding N anion species **20**. Subsequent nucleophilic attack at the 2-position of **4** together with the liberation of the methoxy group produces an intermediate **21**. Then KOtBu abstracts the proton at the 2-position of **21**. The resultant anion of indole nitrogen attacks the cyano group on the side chain to afford **22**. Subsequent prototropy of the imine group completes the formation of **16**.

In conclusion, we have demonstrated that **4** is an excellent electrophile and it reacts regioselectively at the 2-position with nitrogen, sulfur, and carbon centered nucleophiles. Since the 6-nitro group can be transformed into variety of functional groups, this methodology could be applied to the synthesis of various types of 2,3,6-trisubstituted indole derivatives and natural products. The formation of **16** suggests

that if we treat **4** with nucleophiles having 3-amino-2-butenitrile like synthon, the construction of new heterocycles would become possible.

EXPERIMENTAL

Melting points were determined on a Yanagimoto micro melting point apparatus and are uncorrected. Infrared (IR) spectra were recorded with a Shimadzu IR-420 and proton nuclear magnetic resonance (¹H-NMR) spectra with a JEOL GSX-500 spectrometer with tetramethylsilane as an internal standard. Mass spectra (MS) were recorded on a JEOL JMS-SX102A or JEOL JMS-AX5 instruments. Optical rotations were determined on a Horiba SEPA-300 spectrometer. Column chromatography was performed on silica gel (SiO₂, 100—200 mesh, from Kanto Chemical Co., Inc.) throughout the present study.

1-Methoxy-6-nitroindole-3-carbaldehyde (4) from 1-Methoxy-6-nitroindole⁶ (6) — A mixture of POCl₃ (0.97 mL, 10.6 mmol) and anhydrous DMF (5.84 mL, 75.1 mmol) was stirred at rt for 15 min. To the resulting mixture, a solution of **6** (1.00 g, 5.23 mmol) in anhydrous DMF (15 mL) was added and the mixture was stirred at rt for 7 h. After addition of H₂O, the whole was made alkaline with saturated aqueous NaHCO₃ and extracted with EtOAc. The extract was washed with brine, dried over Na₂SO₄, and evaporated under reduced pressure to leave a solid, which was column-chromatographed on SiO₂ with EtOAc–hexane (1:2, v/v) to give **4** (1.08 g, 94 %). **4**: mp 180—182°C (yellow prisms, recrystallized from CHCl₃–Hexane). (*E*)-3-Amino-2,4-di(*p*-chlorophenoxy)-2-butenonitrile (19) from 13 — A mixture of KO^{*t*}Bu (69.3 mg, 0.62 mmol) and **13** (102.3 mg, 0.61 mmol) in anhydrous DMF (2 mL) was stirred at 0 °C for 30 min. After addition of H₂O, the whole was made acidic with 6% HCl, and extracted with EtOAc. The extract was washed with brine, dried over Na₂SO₄, and evaporated under reduced pressure to leave a residue, which was column-chromatographed on SiO₂ with CHCl₃–hexane (1:1, v/v) to give unreacted **14** (27.4 mg, 27%) and **19** (41.5 mg, 41%) in the order of elution. **19**: mp 101–101.5 °C (colorless fine needles,

recrystallized from CHCl_3 –hexane). IR (KBr): 3473, 3361, 2197, 1645, 1489, 1485, 1205, 827 cm^{-1} . $^1\text{H-NMR}$ (CDCl_3) δ : 4.73 (2H, br s, disappeared on addition of D_2O), 4.86 (2H, s), 6.92–6.95 (4H, m), 7.29 (2H, d, $J=9.0$ Hz), 7.31 (2H, d, $J=9.0$ Hz). *Anal.* Calcd for $\text{C}_{16}\text{H}_{12}\text{Cl}_2\text{N}_2\text{O}_2$: C, 57.33; H, 3.61; N, 8.36. Found: C, 57.14; H, 3.61; N, 8.33. Two protons attached to the amino group appeared as a singlet proving that they are equivalent and **19** is an *E* isomer. If **19** is a *Z* isomer, the two protons should be non-equivalent because of hydrogen bonding to phenoxy oxygen.

X-Ray Crystallographic Analysis of 18 — The reflection data were collected at rt on a Rigaku AFC-5R diffractometer with graphite monochromated $\text{CuK}\alpha$ radiation ($\lambda=1.54178$ Å). The structures were solved by direct methods using MITHRIL and refined by the full-matrix least squares. The non-hydrogen atoms were refined anisotropically. All calculations were performed using the teXsan crystallographic package.
