22

23 **Abstract**

24 **Purpose:** This study was designed to identify the endogenous retroviruses (ERVs)
25 associated with testis-specific transcripts linked to the Y (TTYs) in the azoospermia
26 factor (AZF)b region. We evaluated the relationship between ERVs, TTY expression
27 patterns, and TTY function in spermatogenesis.

28 **Material and Methods:** Identification of TTY family members in the AZFb region
29 was performed using computational screening. After investigating the relationship
30 between ERV genome and TTY expression patterns. We screened genomic PCR
31 products from *TTY13* amplified from 790 individuals: 275 azoospermia patients, 285
32 oligozoospermia patients, and 230 fertile males in Japanese subjects.

33 **Results:** Computational screening revealed three TTY family members (*TTY9*, *10*, and
34 *13*) regulated by ERVs in the AZFb region. Homologous recombination between LTR
35 of a *TTY13*-associated ERV, HERV-K14C, resulted in *TTY13* deletion events. These
36 deletions were more frequent in azoospermic and oligozoospermic patients than in
37 fertile males. Specifically 15.63% of the azoospermia group had only the deletion
38 variant, 10.88% of the oligozoospermia group, and 0% of the fertile controls indicating
39 that there is an association between the rate of homologous recombination and the
40 severity of spermatogenesis failure that shows statistical significances ($p < 0.05$).

41 **Conclusions**

42 The finding of novel micro-deletions due to ERV in the AZFb indicated that our study
43 raises the possibility that specific variations in genomic structure may contribute to
44 some forms of human idiopathic male infertility.

45 **Introduction**

46 Approximately 8% of the human genome is composed of ERVs and related sequences ¹.
47 It is generally believed that exogenous retrovirus infected ancient host germ-cells and
48 formed proviruses in their genomes. The majority of ERV families integrated into the
49 primate genome after the divergence of New World and Old World monkeys, and
50 subsequently amplified several times during primate evolution ². ERVs contribute to the
51 host genome and can be associated with the pathogenesis of autoimmune disease,
52 psychiatric disease, cancers, and male infertility ^{3,4}. Retroviral genomes are flanked by
53 LTRs that encode regulatory elements that potentially provide enhancers, alternative
54 promoters, and polyadenylational signals to nearby cellular genes ⁵. Several studies
55 report that EVR LTR elements function as promoters and enhancers of gene expression
56 in specific tissues and cell lines ³.

57 All Y-chromosome sequences can be classified as X-transposed, X-degenerate,
58 or ampliconic. The ampliconic regions comprise eight palindromes that share more than
59 99.9% sequence homology ⁶. Microdeletions on the long arm of the Y chromosome
60 contribute to male infertility. The AZF region is thought to be rich in various functional
61 genes and transcription units, and is essential for spermatogenesis ⁷. Although the AZF
62 region is divided into three regions, AZFa, AZFb, and AZFc, according to chromosomal
63 position and testicular pathology, part of AZFb region is reported to overlap with part of
64 AZFc ⁸. Many such microdeletions identified to date result from non-reciprocal

65 intrachromosomal recombination events between homologous sequences and lead to
66 genome variation and rearrangement ⁹.

67 Deletions of AZFa can result from non-reciprocal homologous recombination events
68 between two HERV sequence elements ^{6,10}. The AZFb region consists of long tracks of
69 repeated sequences. Genes reside in this interval, and most of them encode testis-
70 specific transcripts ^{8,11}. The AZFc region is composed entirely of amplicons, and it is
71 particularly susceptible to deletion. The palindromes in the AZFc region consist of a
72 complex of several small segments called sub-amplicons ¹². Deletions in the AZFc
73 region were shown to result from recombination between two direct repeats, sub-
74 amplicon b2 and b4 ¹². Therefore, microdeletions have removed several testis-specific
75 transcription and expression units, and reduction in the copy number of AZFc genes
76 could cause reduced sperm production ^{6,8,13,14}.

77 Transcripts of the TTY family are dispersed throughout ampliconic and X-degenerated
78 regions of the Y chromosome; however, their role in spermatogenesis, predicted by *in*
79 *silico* analysis, is still poorly understood. Although the TTY family was thought to be
80 expressed exclusively in testis, recent studies have shown some TTYs are not always
81 testis-specific ^{8,15}.

82 This study was designed to identify the ERVs associated with TTYs in the AZFb region
83 using computational screening. We sought to understand the relationship between ERVs,
84 TTY expression patterns, and TTY function in spermatogenesis in Japanese subjects.

85 **Materials and Methods**

86 **Study population**

87 The Ethics Committee of Kanazawa University Hospital approved the study and
88 informed consent was obtained from all participants. From April 2006 to March 2009,
89 we recruited patients with azoospermic and oligozoospermic ejaculate. We excluded
90 individuals with abnormal karyotypes and Y-chromosomal microdeletions. Some
91 patients with azoospermia underwent open testicular biopsy or retrieval of sperm from
92 testicular tissues for histological evaluation and/or TESE in a pilot study. Normal
93 testicular samples were obtained from obstructive azoospermic patients who had
94 undergone a diagnostic testicular biopsy. After this pilot study, we performed the
95 genotype analysis of fertile males (controls) and patients with azoospermia or
96 oligozoospermia. Our control group comprised 230 male volunteers, all of whom were
97 healthy young men who had fathered at least one healthy child without any assisted
98 reproductive procedures.

99 **Histological evaluation and selected subjects in the pilot study**

100 To diagnose the spermatogenic pattern, samples were obtained from at least three
101 different areas in the testis. Testicular histology was classified into four categories:
102 hypospermatogenesis, MA, SCO, and tubular sclerosis.
103 Thirty-three subjects were selected and grouped; Tubular sclerosis (a, no. 1-5) and SCO
104 subjects (b, no. 6-10) represent histologically no cells in the tubular section and no germ

105 cells but SCO in the whole seminiferous tubule, respectively. MA (c, no.11-20)
106 represent no spermatids or sperms, despite much mitotic activity. Hypospermatogenesis
107 subjects (d, no.21-30) represent the reduction in the number of germ cells at all stages.
108 All affected cases show azoospermia in the ejaculate. Normal spermatogenesis (d,
109 no.31-33) shows normal appearance histologically.

110 **Mapping and computational screening for ERV-related TTYs**

111 GenBank data for the human Y chromosome in contig NT_011875 was used in this
112 study. RefSeq mRNAs and genomic loci were identified by the RepeatMasker program
113 (<http://repeatmasker.genome.washington.edu>) with various repeat element consensus
114 sequences from the Repbase Update ¹⁶. After analyzing RefSeq mRNA sequences, we
115 reconstructed the genomic structure of ERV-related TTY family members using
116 PipMaker (<http://pipmaker.bx.psu.edu>).

117 **Preparation of genomic DNA and RNA samples**

118 Testis tissue RNAs were isolated from infertile TESE patients using Trizol reagent
119 (Invitrogen, Carlsbad, CA, USA). Total RNA from male human tissues and from human
120 ovary was purchased from Clontech (Mountain View, CA, USA). Pure mRNA was
121 obtained using the PolyA Tract mRNA isolation system (Promega, Madison, WI, USA).
122 All genomic DNA was isolated from peripheral blood samples with a genomic-tip kit
123 (Qiagen, Hilden, Germany).

124 **RT-PCR amplification**

125 cDNA samples from human total RNA were synthesized with MMLV-derived reverse
126 transcriptase with oligo (dT) and random hexamer primers (Promega). Genomic PCR
127 and RT-PCR reactions were carried out with LA Taq Hot Version kit and a standard
128 PCR kit supplied by Takara (Kyoto, Japan). Primer information and accession numbers
129 are documented in supplementary Table ([http://web.kanazawa-](http://web.kanazawa-u.ac.jp/~med29/andrology/supplementary.html)
130 [u.ac.jp/~med29/andrology/supplementary.html](http://web.kanazawa-u.ac.jp/~med29/andrology/supplementary.html)), and primer positions are shown Fig.
131 1C,D, and E. As a positive control, *GAPDH* was amplified.

132 **Sequencing of deletion junctions**

133 PCR products were sequenced on an ABI 337 DNA sequencer. The same primers that
134 had been used for amplification were used, along with the BigDye Terminator version
135 3.1 Cycle Sequencing Kit (Applied Biosystems, Foster, City, CA, USA) for the
136 sequencing reactions.

137 **Genomic DNA and semen examination**

138 All blood samples were derived from Japanese subjects. The control group comprised
139 230 confirmed fertile male volunteers. All infertile patients had normal karyotypes.
140 Deletions of AZF region were performed as described previously¹⁴. These infertile
141 patients were classified as having azoospermia or oligozoospermia ($<20 \times 10^6 \text{ ml}^{-1}$) in
142 the ejaculate. By these criteria, 275 patients had azoospermia, and 285 patients had
143 oligozoospermia.

144 **Statistical analysis**

145 Data were analyzed using Statistical Package for the Social Sciences statistical software
146 version 11.0 (SPSS, Chicago, IL, USA). The Mann-Whitney test was used to determine
147 whether there was any significant difference in genotype frequencies between the
148 normal control and infertile male groups. The value of $P < 0.05$ was taken to be
149 statistically significant.

150 **Results**

151 **Genomic structure and position of three ERV-related TTY family members**

152 We screened the Y-chromosome genomic contig (NT_011875) from GenBank with the
153 RepeatMasker program and identified three candidate ERV-related sequences: *TTY9*,
154 *TTY 10*, and *TTY 13*, and constructed genomic structures using PipMaker. *TTY9*, *TTY 10*,
155 and *TTY 13* were dispersed throughout the AZFb region between P4 and IR2 (Fig. 1B).
156 On the basis of computational analysis, we determined the structure and Y-chromosome
157 location of the three ERV-derived transcripts (Fig. 1B).

158 Two copies of *TTY9*, *TTY9A* and *TTY9B*, are identical (Fig. 1B); this identity most
159 likely results from the duplication of P4. Internal sequences of ERV3 provided the first
160 exon and the promoter region for *TTY9* (Fig. 1C). Using TRANSFAC[®] Professional
161 version 10.1 with a strict threshold (core match: 1 and matrix match: 0.95~1), we found
162 six binding sites for multiple transcription factors in the promoter region distributed
163 upstream of the transcription starting site.

164 *TTY10* contained two types of ERV-related sequences, LTR12B and LTR19C. LTR12B
165 provided the 3rd and 4th exons of *TTY10*, and LTR19C contributed to the 5th and 6th
166 exons of *TTY10* (Fig. 1D). The 4th and 5th exons encoded the ORF indicating that both
167 ERVs, LTR12B and LTR19C, harbored exons and functional coding regions.
168 *TTY13* contained HERV-K14C, including both LTRs and partially deleted internal
169 sequences (5'LTR-gag-pro-env-3'LTR, and an *AluYd* insert), spanned the last two
170 exons of *TTY13*. HERV-K14C provided the 5th exon, which contained an ORF, and the
171 6th exon (Fig. 1E).

172 **Expression patterns of the ERV-related TTY family**

173 We used RT-PCR to examine the expression profiles of TTYs in various human tissues.
174 The TTY family is thought to be exclusively or predominantly expressed in the testis,
175 consistent with their location on the Y chromosome. RT-PCR analysis revealed that
176 *TTY9* was expressed in testis and kidney and that *TTY10* was expressed in all tissues
177 examined except the ovary (Fig. 2). In contrast, *TTY13* expression was testis-specific.
178 Although *TTY9* and *10* transcripts were observed in other tissues, the transcripts seemed
179 to be most abundant in testis. A number of genes and transcripts are dispersed
180 throughout AZFb on the MSY, and individual deletions of these sequences are thought
181 to cause failure of spermatogenesis. Therefore, we suggest that the ERV-related TTYs
182 participate in spermatogenesis. To investigate the relationship between ERV-related
183 TTYs and spermatogenesis, we analyzed the genomic DNA that encodes TTYs and

184 testis-specific RNAs from patients that present with different types of spermatogenic
185 failure and the same regions of genomic DNA from normal testes.

186 **PCR analysis of genomic DNA in the ERV-related TTY family**

187 We amplified the genomic regions flanking each ERV-related TTY to avoid amplifying
188 other ERV-related sequences in the genome (Fig. 3A). The expected size of the PCR
189 product with the ERV associated with *TTY13*, HERV-K14C, was 6073 nucleotides, and
190 PCR reactions identified three genotypes; intact 6,703-bp product, a smaller 668-bp
191 product, and both products (Fig. 3A). Both the 6,703-bp product and a smaller 668-bp
192 product were amplified from most patients, but seven individuals (1, 7, 14, 15, 22, 26,
193 and 33) presented with only the intact product. In addition, some samples (patients 3, 13,
194 and 27) only yielded only the smaller 668-bp product.

195 To confirm of this finding, we applied other STS marker to all subjects. The primers
196 were designed that one was located in deletion discrepancy (primer pair; S5, AS5) and
197 the other was resided in flanking region of *TTY13* locus ((primer pair; S6, AS6). We
198 estimated that PCR product was not detected in our subjects when deletion was
199 occurred. As depicted in Fig 3A, three individuals who showed smaller 668-bp product
200 which were not revealed any other bands in their genomic DNAs.

201 **RT-PCR analysis of testicular RNA in the ERV-related TTY family**

202 We also analyzed testis RNA from individual infertile patients and normal controls
203 using RT-PCR. No significant relationships between expression of the ERV-related

204 TTY families and idiopathic infertility were detected (Fig. 3B). We found that the
205 ERV-related TTY family was transcribed from testes with tubular sclerosis and those
206 with no germ cells (Fig. 3B a and b) suggesting these TTYs may play a role in the
207 somatic cells of testis tissues.

208 However, in three samples (3, 13, and 27) from three separate histological categories
209 (tubular sclerosis, MA, and hypospermatogenesis) intact *TTY13* was not transcribed;
210 this RT-PCR analysis was consistent with the genomic DNA analysis in that there was
211 only one smaller transcript in these individuals.

212 **TTY13 deletion junction indicates homologous recombination**

213 In our pilot study, the smaller *TTY13* PCR product seen in patients 3, 13, and 27
214 indicates that these individuals harbor a deletion in this region of their genome. To test
215 this hypothesis, we sequenced the PCR amplified DNA from this genomic region. As
216 shown in Fig. 4, the sequences amplified from these patients align with the 5' LTR and
217 3' LTR of HERV-K14C from the *TTY13* locus. This analysis also revealed a stretch of
218 149 overlapping sequences shared by the 5' LTR, the 3' LTR, and the genomic DNA,
219 suggesting that this stretch is a homologous recombination junction point. This stretch
220 of genomic DNA has an overall sequence identity of approximately 88% with the LTRs,
221 and some regions of the junction point showed perfect matches with both LTRs (Fig.
222 4A). The homologous recombination event eliminated 5,405 nucleotides—including
223 introns, the last two exons, and the *AluYd* insert—from the AZFb region (Fig. 4B). This

224 result suggested that *TTY13* was subject to the gain and subsequent loss of HERV-K14C
225 sequences, resulting in an interruption of *TTY13* expression.

226 **Frequency of homologous recombination *TTY13* variant in fertile and infertile men**

227 Infertile individuals, specifically patients 3, 13, and 27, harbored the deletion variant of
228 the *TTY13* locus. Therefore, to estimate the frequency of homologous recombination
229 associated with idiopathic male infertility, we screened genomic PCR products from
230 *TTY13* amplified from 790 individuals: 275 azoospermia patients, 285 oligozoospermia
231 patients, and 230 fertile males (Table). The mean age of proven fertile control males
232 was 31.2 ± 4.5 years; the ages ranged from 20 to 43 years with a median of 31 years.

233 The mean and median sperm concentrations were $105.6 \pm 78.8 \times 10^6 \text{ mL}^{-1}$ and $83.2 \times$
234 10^6 mL^{-1} , respectively; the range of sperm concentrations was $2.2 \times 10^6 \text{ mL}^{-1}$ to $438 \times$
235 10^6 mL^{-1} .

236 All the samples were tested with two of primer set for genomic DNA amplification to
237 confirm the deletion event. The most common genotype, representing 82.4% of all
238 individuals, had both deletion and intact (del/int) variants of HERV-K14C from the
239 *TTY13* locus in genomic DNA.

240 Interestingly, individuals harboring only the deletion variant were restricted to infertile
241 patients, and none were observed among the fertile controls. In addition, the percentage
242 of individuals that carried only the deletion variant within a group was correlated with
243 the severity of spermatogenic failure in that group. Specifically 15.63% of the

244 azoospermia group carried only the deletion variant, 10.88% of the oligozoospermia
245 group, and 0% of the fertile controls (Table). These results indicate that there is an
246 association between the rate of homologous recombination and the severity of
247 spermatogenesis failure and that this association is statistically significantly ($p < 0.05$).
248 Additionally in the fertile control group, the genotype with only an intact *TTY13* locus
249 occurs at a relatively high frequency.

250 **Discussion**

251 Many researchers who study male infertility have investigated deletions of ampliconic
252 sequences in the AZFa, AZFb, and AZFc regions. Microdeletions in the AZFa regions
253 are thought to result from homologous recombination events due to human ERVs^{10, 17}.
254 Some studies reporting on deletion breakpoints in P5/proximal-P1 (AZFb), P5/distal-P1,
255 P4/distal P1 explained only those deletions resulting from direct repeat sequences⁸.

256 Male infertility and several other human diseases result from recurrent DNA
257 rearrangement due to homologous recombination involving unstable genomic regions³.
258 Here, we report that ERVs influence the expression of *TTY9*, *TTY10*, and *TTY13* in the
259 AZFb region and that the ERV in *TTY13*, HERV-K14C, mediates recurrent homologous
260 recombination events. For example, ERV3 acts as promoter for *TTY9* (Fig. 1C).
261 Moreover, ERV sequences were incorporated into 3' exons of *TTY10* and *TTY13* and
262 are presumed to contribute to *TTY10* and *TTY13* transcriptional termination (Fig. 1D,
263 E).

264 Unlike TTY9 and TTY10, both the intact and the deletion form of *TTY13* (6073
265 and 668 bp, respectively) are present. During mitosis or meiosis, sister chromatids
266 exchange genetic information through homologous recombination via
267 intrachromosomal rearrangement^{18, 19}. In addition, a single chromatid fold-back lariat
268 mediated by directly oriented repeats can lead to non-reciprocal crossing-over and cause
269 excision of the lariat (Fig. 4). This intrachromatid homologous recombination can
270 occur in both somatic and germ cells²⁰. When it occurs in germ cells, the new genetic
271 deletion variant may be directly transmitted to the progeny.

272 We observed both the intact and the deletion form of *TTY13* (6073 and 668 bp,
273 respectively) in genomic DNA, indicating that recombination events are frequent and
274 occur predominantly by the LTR mechanism we propose. In addition, only 65 (20
275 infertile and 45 fertile) males harbored only the intact HERV-K14C sequences,
276 suggesting that neither the intact nor deleted form is fixed in the human population.

277 In particular, the HERV-K elements, members of the ERV family, have been
278 continuously multiplying in the human genome, which has led to polymorphism in the
279 human population^{21, 22}. HERVs become inactivated over time, and inactivated HERVs
280 can lead to solitary LTRs, which result from homologous recombination between the
281 two LTRs flanking the provirus and the subsequent deletion of the internal sequence²³,
282²⁴. Some genetic variation was due to the presence of HERV-K solitary LTRs instead of
283 the full-length counterpart in a small number of human individuals. Homologous

284 recombination between the 5' and 3' LTRs of HERV-H resulted in the presence of
285 intact and deleted variants in the same individual, suggesting that this genetic variation
286 is due to an LTR-LTR excision event in humans²⁵.

287 We proposed that HERV-K14C mediates homologous recombination events on
288 the human Y chromosome by a similar mechanism. Screening of 790 (275 azoospermia,
289 285 oligozoospermia, and 230 fertile) males demonstrated that a subpopulation of
290 infertile males harbored only the deletion variant (n = 74), whereas 567 (219
291 azoospermia, 247 oligozoospermia, and 185 fertile) of 790 samples, representing three
292 fertility classes (azoospermia, oligozoospermia, and fertile), contained both the intact
293 (6,073 bp) and deletion (668 bp) forms of *TTY13* (Table 2). The deletion variant was
294 more common in infertile males and seemed to occur more frequently when the
295 symptoms were more severe.

296 Repeat sequences are dispersed at low densities in ampliconic regions of the Y
297 chromosome. In contrast, ERV-related sequences were more common in ampliconic
298 region than in human genomic sequence on average^{26,27}. The evolutionary dynamics of
299 the Y chromosome are generally much faster than those of the autosomes and the X
300 chromosome, owing to deletions and mutations^{28,29}. Our data suggest that ERVs may
301 lead to genomic instability by inducing new insertions and by causing deletions via
302 homologous recombination of intrinsic ERV sequences, particularly LTRs. These

303 deletion events may be associated with some cases of male infertility that are due to
304 genomic instability.

305 **Conclusion**

306 The finding of novel micro-deletions due to ERV in AZFb indicated that our study
307 raises the possibility that specific variations in genomic structure may contribute to
308 some forms of human idiopathic male infertility. These observations emphasize the
309 necessity of investigating genome structure and transcripts of Y chromosome in detail.

427 **Fig. legends**

428 **Fig. 1 Schematic diagrams of a Y-chromosome overview.** (A) Overview of the Y
429 chromosome: gray-scale boxes indicate pseudoautosomal (black), euchromatic (white),
430 and heterochromatin (light gray) sequences. (B) The enlarged schematic representation
431 of a palindrome region: gray-scale boxes indicate X-degenerate (pale gray),
432 heterochromatin (medium gray), and ampliconic (dark gray) regions, palindromes are
433 illustrated by dark gray arrows (P1-8) and AZFa,b,c regions. The locations and
434 directions of ERV-related TTYs in AZFb are indicated as black triangles. The genomic
435 structures of the ERV-related (C) *TTY9*, (D) *TTY10*, and (E) *TTY13* are illustrated.
436 Boxes represent exons, and ORF are in black. ERVs are depicted by large dark gray
437 arrows. Splicing is represented by solid lines, and small black arrows indicate PCR
438 primer locations.

439

440 **Fig. 2 Expression profiles of ERV-related TTYs.** RT-PCR analysis of *TTY9*, *TTY10*,
441 and *TTY13* expression in various human tissues. *GAPDH* was used as a positive control.

442

443 **Fig. 3 PCR amplification of genomic DNAs and RT-PCR analysis of testis cDNA**
444 **from azoospermic patients.**

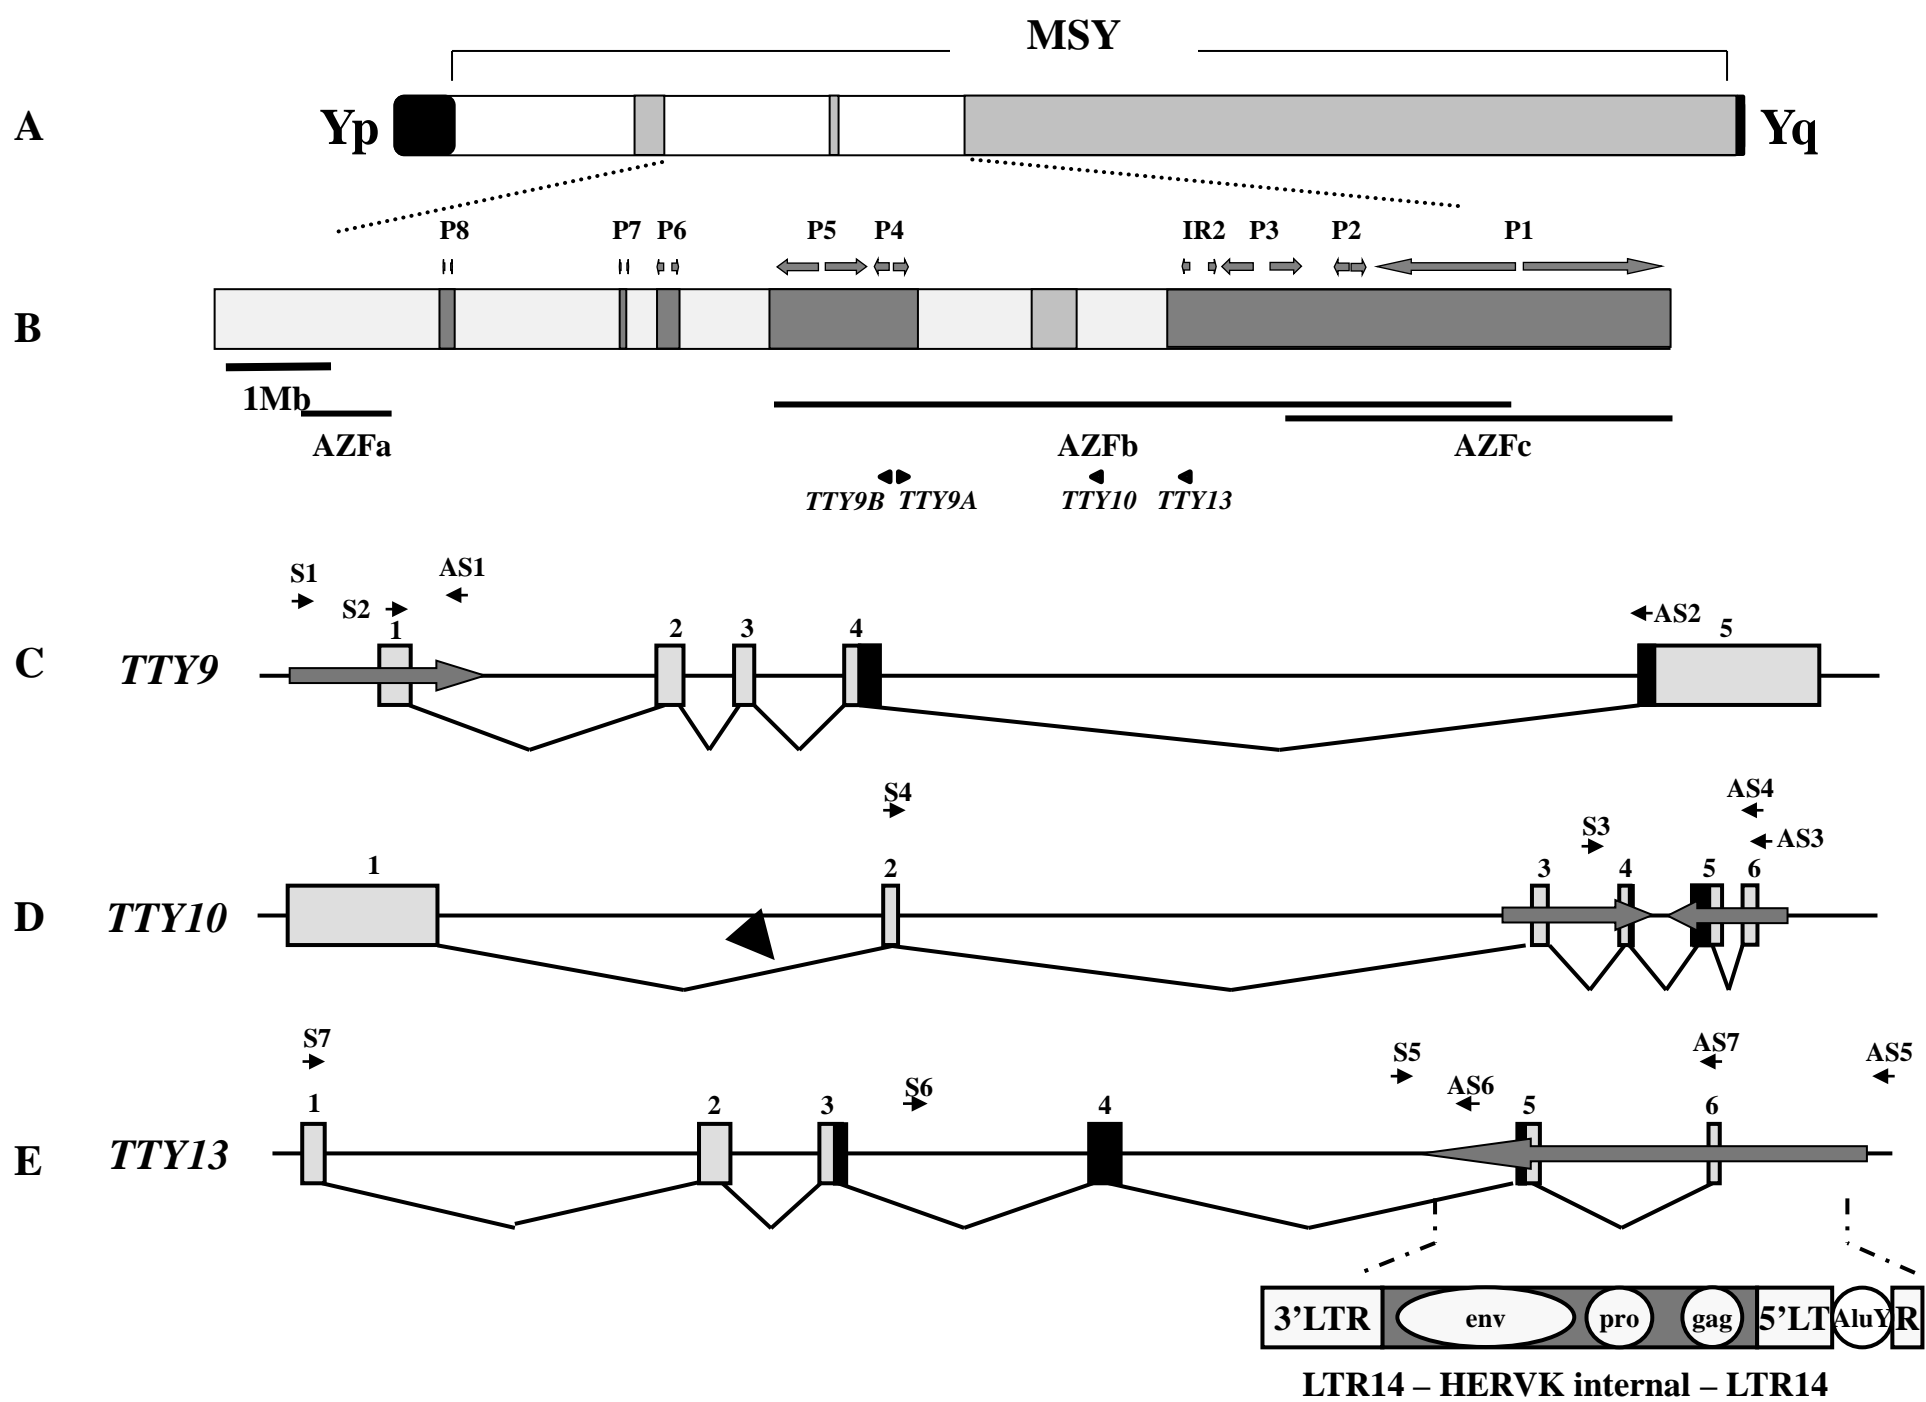

445 (A) PCR amplification of genomic DNA from peripheral blood cells, (B) RT-PCR of
446 testis cDNA.

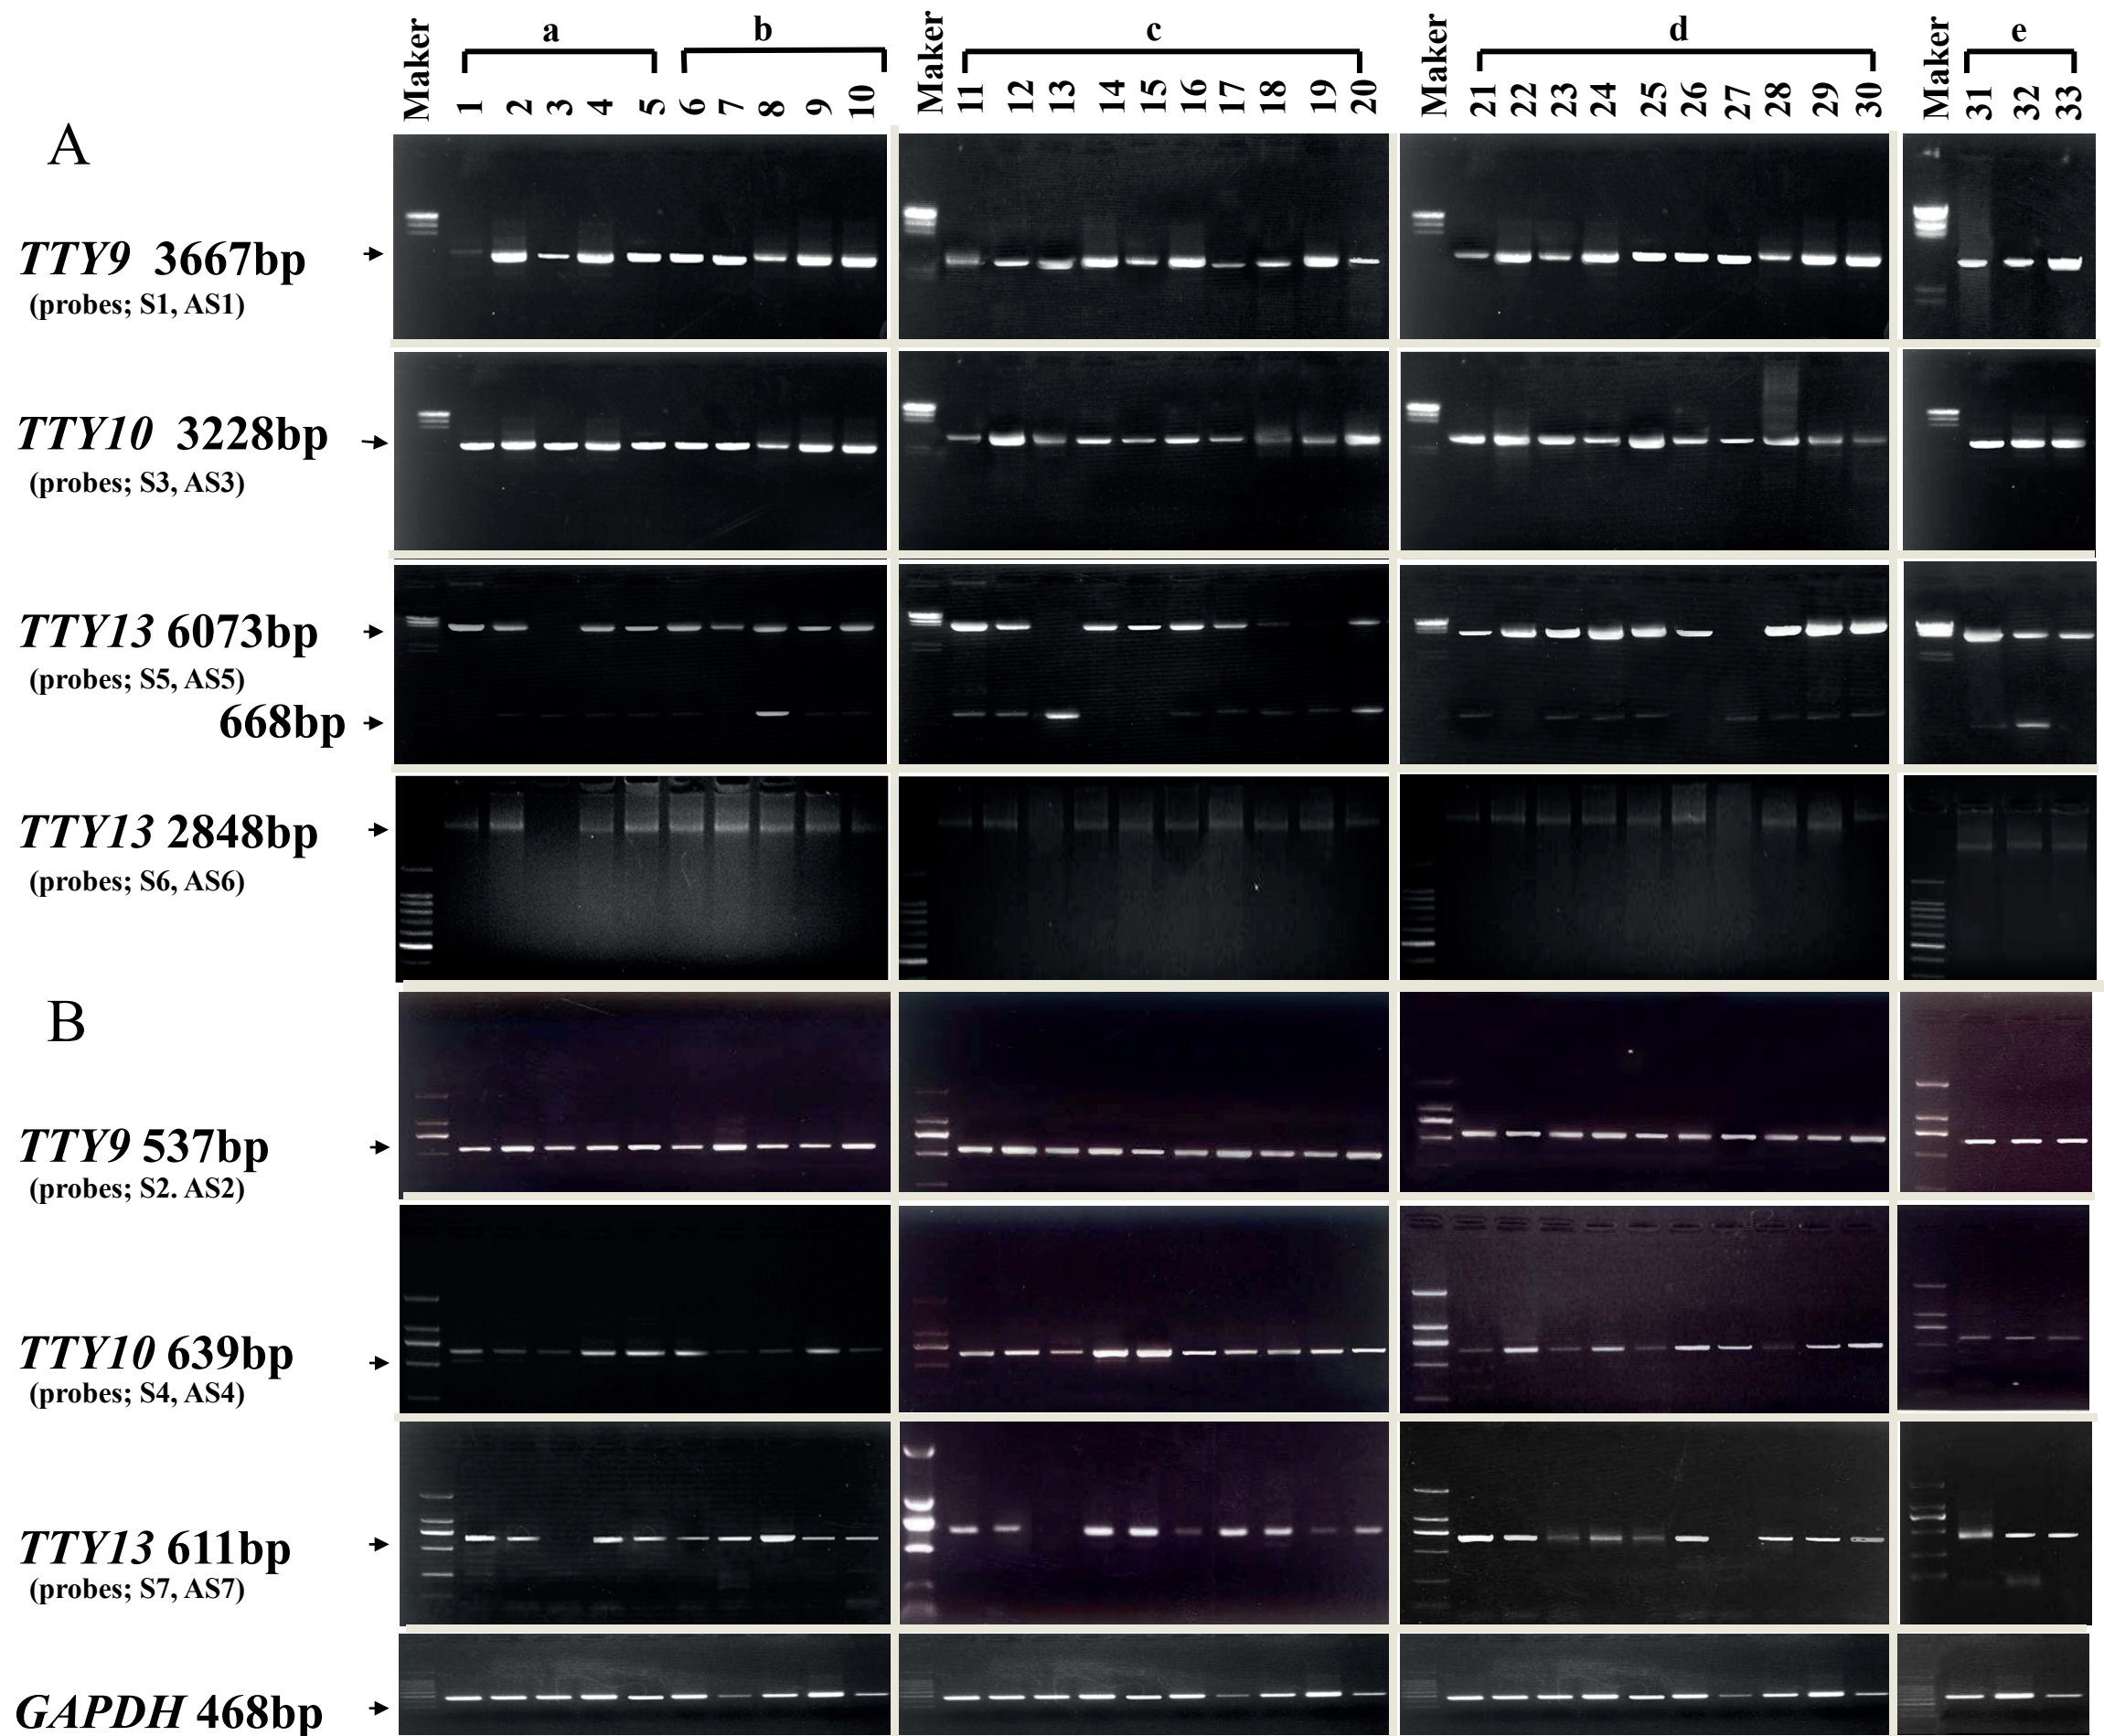

447 (A) and (B): M, size markers; 1-33, individual male subjects. The subjects are grouped
448 as follows: a, Tubular sclerosis; b, SCO; c, MA; d, hypospermatogenesis; and e, normal
449 spermatogenesis (Materials and Methods). *GAPDH* was used as a positive control.

450

451 **Fig. 4 *TTY13* deletion junction indicating homologous recombination between 5'**
452 **and 3' LTR of HERV-K14C.** (A) Analysis of sequence data from the 668-bp deleted
453 form, the 5' LTR, and the 3' LTR. The breakpoints between both LTRs are indicated
454 with gray boxes. Open boxes illustrate the genomic region flanking HERV-K14C. (B)
455 Schematic representation of the putative homologous recombination between the 5' and
456 3'LTRs. Gray pentagons depict recombination spots. The black box indicates an *AluYd*
457 insert.

Table The frequency of TTY13 genotypes in infertile male patients and normal subjects

| Variant types | number | intact | int/del | Deletion |
|--------------------|---------|------------|--------------|-------------|
| Normal controls | | | | |
| Known fertility | n = 230 | 45 (19.6%) | 185 (80.4%) | 0 (0%) |
| Infertile patients | | | | |
| Oligozoospermia* | n = 285 | 7 (2.46%) | 247 (86.66%) | 31 (10.88%) |
| Azoospermia* | n = 275 | 13 (4.72%) | 219 (79.63%) | 43 (15.63%) |

int/del; intact+deletion variants

* Mann-Whitney U test ($p < 0.05$) when compared with known fertility group.
