A short step synthesis of lespedamine

A SHORT STEP SYNTHESIS OF LESPEDAMINE[1]

Abstract—— A convenient synthetic method for 1-hydroxy-, 1-methoxy-, and 1-acetoxy-2-oxindole was disclosed starting from methyl 2-nitrophenylacetate. A five-step synthesis of lespedamine was achieved utilizing this method.

In this report, we describe a practical synthetic method for 1-hydroxy-2-oxindole derivatives and a short step synthesis of lespedamine (1),[2,3] one of eight naturally occurring 1-methoxyindole derivatives.[4]

I. Syntheses of 1-Hydroxy-2-oxindole Derivatives

Various synthetic methods so far reported for 1-hydroxy- (2) and 1-methoxy-2-oxindole (3) are known to give unsatisfactory results.[5] However, we found that the readily available methyl 2-nitrophenylacetate (4) simply upon treatment with zinc (20 mol eq.) and ammonium chloride (3.8 mol eq.) in methanol for 3h afforded 2[6] in 48% yield. When an excess amount of reducing agents was used or a longer reaction time was adopted, the yield of 2 was decreased mainly due to its sensitivity toward reductive decomposition, resulting in the formation of 2-oxindole.

We have also found that a significant amount of 2 was lost by the formation of a complex[7] with zinc iron, which was rather insoluble in organic solvents. The structure of the complex was tentatively assigned to be 5 based mainly on its mass spectrum which showed the ratio of 2 and zinc iron to be 2 to 1.

Direct treatments of the reaction mixture, obtained by the reaction of 4 with zinc and ammonium chloride, with diazomethane and acetic anhydride and pyridine were found to give 1-methoxy- (3)[8] and 1-acetoxy-2-oxindole (6)[9] in 77% and 70% overall yields, respectively. Furthermore, hydrolysis of 6 with sodium carbonate afforded 2 in 94% yield.

II. Synthesis of Lespedamine

The reaction of 3 with ethylene dibromide in the presence of sodium hydride afforded spiro compound (7)[10] in 90% yield. Subsequent treatment of 7 with aq. dimethylamine (50 mol eq.) and its hydrochloride (9 mol eq.) in N,N-dimethylformamide produced the desired 3-(2-N,N-dimethylaminoethyl)-1-methoxy-2-oxindole (8)[11] in 54% yield, together with 10% yield of a phenylhydroxylamine derivative (9).[12] The reduction of 8 with lithium aluminum hydride ($LiAlH_4$) in ether was found to produce 3-(2-N,N-dimethylaminoethyl)-2-hydroxy-1-methoxy-2,3-dihydroindole (10)[13] in 62% yield as a mixture of diastereoisomers. The compound (10) was unstable and instantaneously changed by treatment with aq. hydrochloric acid to lespedamine[14] (1) in 95% yield. On the basis of the above results, the final step was improved as follows. Thus, after reduction of 8 with $LiAlH_4$, the reaction mixture was treated briefly with aq. hydrochloric acid. By this modification, lespedamine (1) was prepared in 64% yield directly from 8. Thus, the total synthesis[3] of 1 was achieved in five steps with 24% overall yield from 4. The spectral data of synthetic material and melting point of its picrate were identical with those of lespedamine.[2] In conclusion, building blocks such as 2, 3, and 6 for 1-hydroxyindole derivatives have now become readily available from 4 in excellent yields. Investigation of their reactions and preparation of other naturally occurring 1-methoxyindole derivatives are currently in progress.
