### ABSTRACT

**Relapsed osteosarcoma is a recalcitrant tumor. A patient's cisplatinum (CDDP)-resistant relapsed osteosarcoma lung metastasis was previously established orthotopically in the distal femur of mice to establish a patient-derived orthotopic xenograft (PDOX) model. In the present study, the PDOX models were randomized into the following groups when tumor volume reached 100 mm<sup>3</sup>: G1, control without treatment; G2, CDDP (6 mg/kg, intraperitoneal (i.p.) injection, weekly, for 2 weeks); gemcitabine (GEM) (100 mg/kg, i.p., weekly, for 2 weeks) combined with docetaxel (DOC) (20 mg/kg, i.p., once); temozolomide (TEM) (25 mg/kg, p.o., daily, for 2 weeks) combined with irinotecan (IRN) (4 mg/kg i.p., daily for 2 weeks). Tumor size and body weight were measured with calipers and a digital balance twice a week. After 2 weeks, all treatments significantly inhibited tumor growth except CDDP compared to the untreated control: CDDP:  $p = 0.093$ ; GEM+DOC:  $p = 0.0002$ , TEM+IRN:  $p < 0.0001$ . TEM combined with IRN was significantly more effective than either CDDP ( $p = 0.0001$ ) or GEM combined with DOC ( $p = 0.0003$ ) and significantly regressed the tumor volume compared to day 0 ( $p = 0.003$ ). Thus the PDOX model precisely identified the combination of TEM-IRN that could regress the CDDP-resistant relapsed metastatic osteosarcoma PDOX.**

### INTRODUCTION

Osteosarcoma is a recalcitrant tumor with greatest incidence in adolescence and in the seventh and eighth decades. First-line therapy for osteosarcoma is high-dose methotrexate (MTX), cisplatinum (CDDP), doxorubicin

(DOX), and ifosfamide, which is ineffective in metastatic osteosarcoma with less than 20% long-term survival and has not improved for many years [1–8].

Temozolomide (TEM) has been tested pre-clinically against osteosarcoma cells combined with a molecular targeting drug [9] and as a single-agent

against osteosarcoma xenograft models [10] as well as in combination with irinotecan (IRN) in a patient-derived orthotopic xenograft (PDOX) model or rhabdomyosarcoma [11].

Trabectedin (TRAB) is an alkylating agent derived from the Caribbean tunicate, *Ecteinascidia turbinata* [11] which has been tested on liposarcoma and leiomyosarcoma patients [12, 13], TRAB arrests cells in the G<sub>2</sub>/M phase of the cell cycle [14], TRAB has shown efficacy against CDDP-resistant bone cancer *in vitro* [15]. TRAB is marketed as Yondelis (Johnson & Johnson, Raritan, NJ) for leiomyosarcoma and liposarcoma [16]. TRAB has been used for recurrent osteosarcoma patients with a 12% partial response rate [17].

The combination of gemcitabine (GEM) and docetaxel (DOC) may be synergistic due to their complementary mechanisms of action of arresting cells in different phases of the cell cycle [19].

We previously reported that a subcutaneous transplant nude-mouse model of a CDDP-resistant osteosarcoma lung metastasis was regressed by tumor-targeting *Salmonella typhimurium* A1-R (*S. typhimurium* A1-R), but was only partially sensitive to the molecular-targeting drug sorafenib, which did not arrest its growth. *S. typhimurium* A1-R was significantly more effective than sorafenib [18].

Toward the goal of individualized precision oncology, our laboratory pioneered the PDOX nude mouse model with the technique of surgical orthotopic implantation (SOI), including pancreatic [19–22], breast [23], ovarian [24], lung [25], cervical [26], colon [27–29], and stomach cancer [30], sarcoma [31–35] and melanoma [36–38].

We subsequently developed a PDOX model from the CDDP-resistant osteosarcoma lung metastasis that recurred after adjuvant CDDP treatment of the patient [8]. The CDDP-resistant metastatic osteosarcoma PDOX was sensitive to TEM and TRAB, but not CDDP. These results showed that the PDOX model of the CDDP-resistant osteosarcoma lung-metastasis could identify potentially, highly-effective drugs for this recalcitrant disease, while accurately maintaining the CDDP resistance of the tumor in the patient [8].

In the present study, we evaluated the efficacy TEM combined with IRT, compared to GEM combined with DOC compared to CDDP on the PDOX model of CDDP-resistant relapsed osteosarcoma.

## RESULTS AND DISCUSSION

### Efficacy of CDDP alone, GEM combined with DOC and TEM combined with IRN on the CDDP-resistant metastatic osteosarcoma PDOX mouse model

After 2 weeks, all treatments, except CDDP, significantly inhibited tumor growth compared to untreated control: CDDP:  $p = 0.093$ ; GEM+DOC:  $p = 0.0002$ , TEM+IRN:  $p < 0.0001$ . TEM combined with

IRN was significantly more effective than either CDDP ( $p = 0.0001$ ) or GEM combined with DOC ( $p = 0.0003$ ) and significantly regressed the tumor volume compare to day 0 ( $p = 0.003$ ) (Figures 1–3).

The CDDP-resistant metastatic osteosarcoma PDOX faithfully replicated the CDDP-resistance of the tumor in the patient. The PDOX model could also identify the TEM-IRN combination which could regress the tumor indicating potential for efficacy in the patient [39]. The utility of the PDOX model is to match the drug to the patient. The TEM+IRN combination appears most promising as TEM alone did not regress the tumor [8].

### Effect of treatment on the body weight of PDOX models

The body weight of treated mice was not significantly different in any group (Figure 4). There were no animal deaths in any group.

### Effect of treatment on the histology of PDOX models

High power microscopy of the original patient tumor demonstrated neoplastic chondroid matrix occupied by anaplastic cells [8]. The tumor had hypercellular areas populated by anaplastic cells displaying nuclear pleomorphism, coarse and hyperchromatic chromatin and abundant mitotic figures (Figure 5A). High-power microscopy of the untreated PDOX tumor showed a solid and chondroblastic appearance similar to the patient's original tumor. Hypercellular areas were filled with cancer cells displaying nuclear pleomorphism and mitotic figures (Figure 5B) [8]. The PDOX tumor treated with CDDP comprised viable cells without apparent necrosis or inflammatory changes similar to the untreated control (Figure 5C). PDOX tumors treated with GEM+DOC showed changes in cancer-cell shape with slight areas of necrosis (Figure 5D). The TEM+IRN treated tumor showed more extensive tumor necrosis which is consistent with tumor regression after this treatment (Figure 5E).

In the largest soft-tissue sarcoma (STS) PDOX study to date, we previously demonstrated a 62% establishment rate among untreated high-grade sarcoma with a median establishment time of 54 days [40]. These results demonstrated that the PDOX model is a practical model for precision oncology for sarcoma patients.

The present results are a good example of precisely identifying a drug, the combination of TEM+ IRN that has potential for efficacy in the patient with CDDP-resistant lung metastatic osteosarcoma.

This result demonstrated the broad potential utility of the PDOX model for sarcoma and likely for other diseases as well with the goal of matching the patient with an effective drug or combination.

Previously-developed concepts and strategies of highly-selective tumor targeting can take advantage of molecular targeting of tumors, including tissue-selective therapy which focuses on unique differences between normal and tumor tissues [41–46].

## MATERIALS AND METHODS

### Mice

Athymic *nu/nu* nude mice (AntiCancer Inc., San Diego, CA), 4–6 weeks old, were used in this study. Animals were housed in a barrier facility on a high efficiency particulate arrestance (HEPA)-filtered rack under standard conditions of 12-hour light/dark cycles. The animals were fed an autoclaved laboratory rodent diet. All animal studies were conducted with an AntiCancer Institutional Animal Care and Use Committee (IACUC)-protocol specifically approved for this study and in accordance with the principles and procedures outlined in the National Institute of Health Guide for the Care and Use of Animals under Assurance Number A3873-1. In order to minimize any suffering of the animals, anesthesia and analgesics were used for all surgical experiments. Animals were anesthetized by subcutaneous injection of a 0.02 ml solution of 20 mg/kg ketamine, 15.2 mg/kg xylazine, and 0.48 mg/kg acepromazine maleate. The response of animals during surgery was monitored to ensure adequate depth of anesthesia. The animals were observed on a daily basis and humanely sacrificed by CO<sub>2</sub> inhalation when they met the following humane endpoint criteria: severe tumor burden (more than 20 mm in diameter), prostration, significant body weight loss, difficulty breathing, rotational motion and body temperature drop [8].

### Patient-derived tumor

The study was previously reviewed and approved by the UCLA Institutional Review Board (IRB #10-001857). Written informed consent was previously obtained from the patient as part of the above-mentioned UCLA Institutional Review Board-approved protocol [8]. A 16-year old patient with localized left-distal-femoral high-grade osteosarcoma underwent CDDP-based neoadjuvant chemotherapy and limb-salvage distal-femoral replacement. The tumor necrosis extent of the primary tumor after CDDP based chemotherapy was 70%. One year later, the osteosarcoma relapsed with three bilateral metachronous pulmonary metastases. The patient was treated with curative surgery at the Division of Surgical Oncology, University of California, Los Angeles (UCLA). The patient did not receive neoadjuvant chemotherapy or radiotherapy prior to lung surgery [8].

### Surgical orthotopic implantation (SOI) for establishment of the PDOX osteosarcoma model

A lung metastasis from the osteosarcoma patient was previously established subcutaneously in mice [18]. Subcutaneously-grown tumors were harvested and cut into small fragments (3–4 mm). After nude mice were anesthetized, a 10 mm skin incision was made on the right thigh, the vastus lateralis muscle was opened and

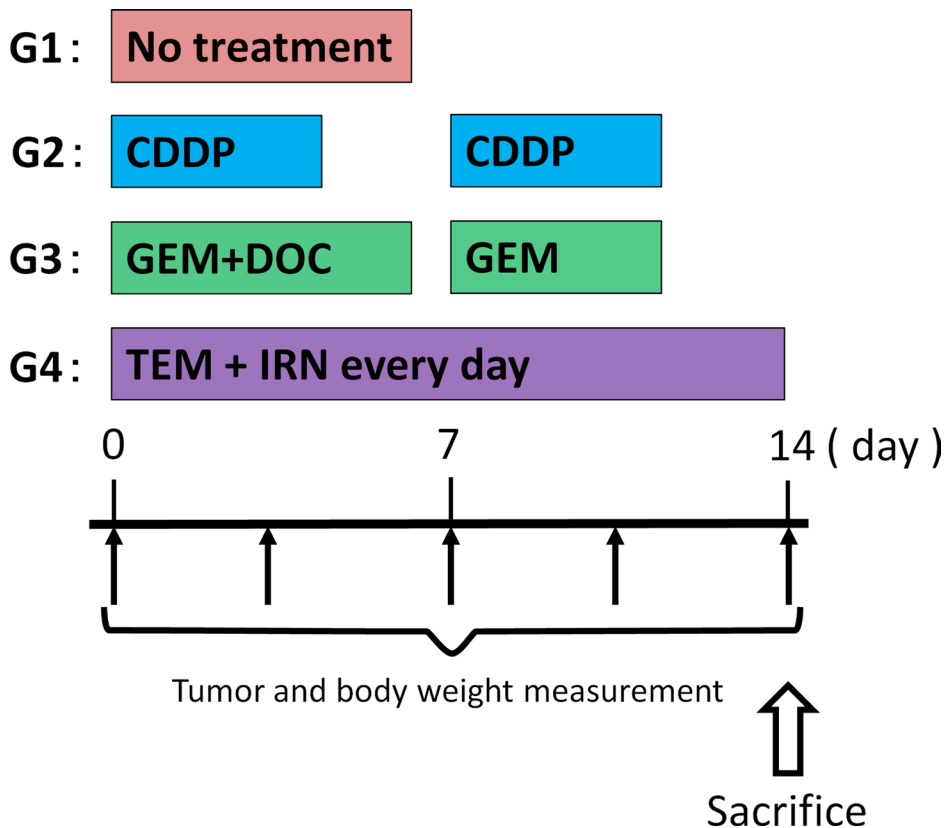

Figure 1: Treatment schema.

**Figure 2: Quantitative efficacy of treatment.** Tumor volume was measured at the indicated time points after the onset of treatment. Please see the Materials and Methods for details.  $N = 8$  mice/group.  $*p < 0.001$

**Figure 3: Photographs of treated and untreated tumors.** Photos of representative treated and untreated osteosarcoma PDOX models.

**Figure 4: Effect of treatments on mouse body weight.** Bar graph shows body weight in each group at pre-treatment and 2 weeks after drug administration. There were no significant differences between each group.

**Figure 5: Effect of treatments on PDOX tumor histology.** Hematoxylin and eosin (H&E)-stained section of the (A) original patient tumor; (B) untreated PDOX tumor; (C) PDOX tumor treated with CDDP; (D) PDOX tumor treated with GEM+DOC; (E) PDOX tumor treated with TEM+IRN. Scale bars: 80  $\mu$ m.

the biceps femoris muscle was split to reach the distal femur. An incision was made in the lateral patello-femoral ligament, sparing the knee joint and then the lateral condyle of the femur was resected. A single 3 to 4 mm tumor fragment was implanted orthotopically into the space to establish a PDOX model. The muscle and wound was closed with 6-0 nylon suture (Ethilon, Ethicon, Inc., NJ, USA) [8, 18].

### Treatment study design

The PDOX models were randomized into the following groups when tumor volume reached 100 mm<sup>3</sup>: G1, control without treatment; G2, CDDP (6 mg/kg, intraperitoneal (i.p.) injection, weekly, for 2 weeks); G3, GEM (100 mg/kg, i.p., weekly, for 2 weeks) combined with DOC (20 mg/kg, i.p., once); G4, TEM (25 mg/kg, p.o., daily, for 2 weeks) combined with IRN (4 mg/kg i.p., daily for 2 weeks) (Figure 1). Tumor sizes and body weight were measured with calipers and digital balance twice a week.

### Histological analysis

Fresh tumor samples were fixed in 10% formalin and embedded in paraffin before sectioning and staining. Tissue sections (3 μm) were deparaffinized in xylene and rehydrated in an ethanol series. Hematoxylin and eosin (H&E) staining was performed according to standard protocol. Histological examination was performed with a BHS system microscope. Images were acquired with INFINITY ANALYZE software (Lumenera Corporation, Ottawa, Canada) [8].
